Coding for memory systems

- Idea: Add redundancy to the data stored in memory bank in order to reduce latency, and increase memory access speed.
- Basic mechanism: Erasure codes allow to add redundancy such that when a memory bank is serving to a processor, another processor can be served simultaneously by re-constructing the data of the busy memory bank (i.e., considering the busy bank as erasure).

Simplest example

Scenario: A processor is accessing to one of the two memory banks. We want to double the capacity, and add another processor. But, this may create bank conflicts. Algorithmic Memory (by Memoir Systems) uses coding to resolve conflicts.

Note: Algorithmic Memory (by Memoir Systems) is using erasure codes (like Reed-Solomon codes). Different codes exist allowing efficiency for different tradeoffs.

Regenerating codes

Regenerating codes allow for trading-off a) the complexity of the circuitry (or bandwidth) used for the recovery of busy bank and b) data bus bandwidth connecting banks to processors.

■ Encoding k memory banks, d_1 to d_k , into n banks by adding n-k parity banks p_1 to p_{n-k}

Regenerating codes

- lacktriangle lpha: Data bus bandwidth connecting banks to each processor
- d: Number of banks connected by recovery circuitry in the event that a busy memory bank needs to be connected to a processor
- \blacksquare β : Amount of data downloaded to the recovery circuitry

Code design for the worst case

- lacktriangle Consider all the processors are interested in the first memory bank, d_1 .
- Serve \mathcal{P}_1 from bank storing d_1 . Use recovery circuitry for the rest of the processors. Total nodes need to satisfy $n \ge 1 + (p-1)d$. As we seek to maximize processors served per memory bank p/n, we set n = 1 + (p-1)d for this analysis.
- Given n = 1 + (p-1)d, the code trades-off the followings
 - Maximize capacity of the system k/n.
 - Total recovery bandwidth per processor: $\max\{\alpha, d\beta\}$.
 - Data bus bandwidth from recovery unit to each processor: α .

Extensions

- Allow for delay instead of worst case code design.
- Memory write operations, and update efficiency.

■ We consider the following scenario:

- We consider the following scenario:
 - We have to store two blocks of data (a, b).

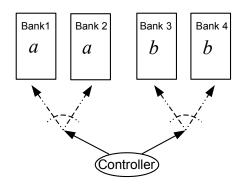

- We consider the following scenario:
 - We have to store two blocks of data (a, b).
 - size(a) = size(b) = size of one memory bank = M.

- We consider the following scenario:
 - We have to store two blocks of data (a, b).
 - $\operatorname{size}(\mathbf{a}) = \operatorname{size}(\mathbf{b}) = \operatorname{size}$ of one memory bank = M.
 - Let (a(1), ..., a(M)) denote M elements of block (a).

- We consider the following scenario:
 - We have to store two blocks of data (a, b).
 - $\operatorname{size}(\mathbf{a}) = \operatorname{size}(\mathbf{b}) = \operatorname{size}$ of one memory bank = M.
 - Let (a(1), ..., a(M)) denote M elements of block (a).
 - Similarly, $\mathbf{b} = (b(1), ..., b(M)).$

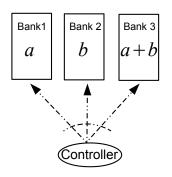

- We consider the following scenario:
 - We have to store two blocks of data (a, b).
 - $\operatorname{size}(\mathbf{a}) = \operatorname{size}(\mathbf{b}) = \operatorname{size}$ of one memory bank = M.
 - Let (a(1), ..., a(M)) denote M elements of block (a).
 - Similarly, $\mathbf{b} = (b(1), \dots, b(M))$.
 - Need to support any 2 reads: (a(i), a(j)), (b(i), b(j)), or (a(i), b(j)).

■ Solution 1: 2-Repetition

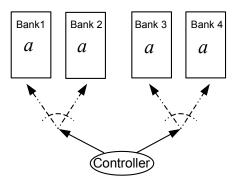

- 4 memory banks to store 2 data blocks \Rightarrow Rate 1/2.
- Total area 4 unit.

Solution 2: XOR code

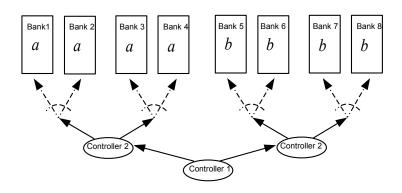

- a + b = (a(1) + b(1), ..., a(M) + b(M)).
- 3 memory banks to store 2 data blocks \Rightarrow Rate 2/3.
- Total area 3 unit + controller circuitry (includes decoder).

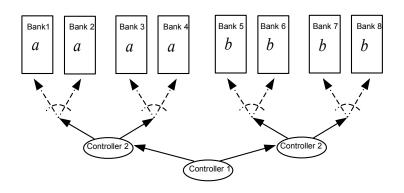

■ Solution 1: 4-Repetition

■ Solution 1: 4-Repetition

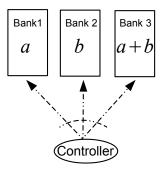

■ Solution 1: 4-Repetition

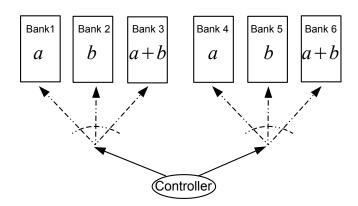

- 8 memory banks to store 2 data blocks \Rightarrow Rate 1/4.
- Total area 8 unit + controller circuitry.

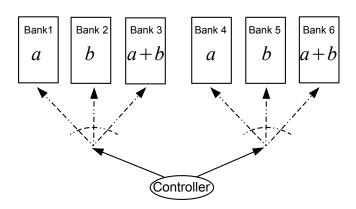

■ Solution 2: 2-Repetition of XOR code

■ Solution 2: 2-Repetition of XOR code

■ Solution 2: 2-Repetition of XOR code

- 6 memory banks to store 2 data blocks \Rightarrow Rate 1/3.
- Total area 6 unit + controller circuitry (includes decoder).

- Total length: **999471** cycles (processor clock).
- Fraction of time memory is accessed (read/write): **0.3045**.
- Fraction of memory access for read: **0.3874**.
- Fraction of memory access for write: **0.6932**.
- At most two fetch instructions in one clock cycles ⇒ At most two memory access in one clock cycle.
- Fraction of cycles when memory is accessed and two memory operations are performed: 0.0746.

At most 2 memory access in one clock cycle.

At most 2 memory access in one clock cycle.

- Possible memory operations in one clock cycle:
 - 1 1 read.
 - 2 1 write.
 - 3 1 read 1 write.
 - 4 2 reads.
 - 5 2 writes.

At most $\underline{2}$ memory access in one clock cycle.

- Possible memory operations in one clock cycle:
 - 1 1 read.
 - 2 1 write.
 - 3 1 read 1 write.
 - 4 2 reads.
 - 5 2 writes.

Both solutions for **2 reads and 1 write** work. ('4-repetition' and '2-repetition of XOR code'.)

Fraction of time memory is accessed (read/write): 0.3045

Fraction of time memory is accessed (read/write): 0.3045

Fraction of cycles when memory is accessed and two memory operations are performed: 0.0746.

Fraction of time memory is accessed (read/write): 0.3045

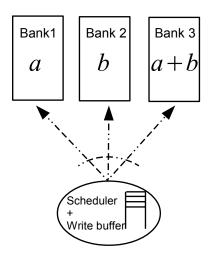

Fraction of cycles when memory is accessed and two memory operations are performed: 0.0746.

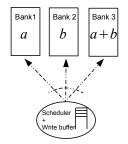

- Most of the instructions do not access memory.
- Bursty access pattern though.
- Very few clock cycles have two simultaneous access to memory.

Fraction of time memory is accessed (read/write): 0.3045

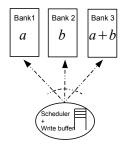

Fraction of cycles when memory is accessed and two memory operations are performed: 0.0746.

- Most of the instructions do not access memory.
- Bursty access pattern though.
- Very few clock cycles have two simultaneous access to memory.
 - Should we design for worst case 'read/write' access pattern?
 - Backlogged write requests can be cleared when
 - (i) no memory access
 - (ii) single memory operation.

- This scheme can server 2 simultaneous read or 1 write.
- Buffer some write requests and clear them when opportunity arise.
- Can a read request for data in write buffer be directly served from write buffer?

- This scheme can server 2 simultaneous read or 1 write.
- Buffer some write requests and clear them when opportunity arise.
- Can a read request for data in write buffer be directly served from write buffer?
- Similar ideas in RAID (with non-volatile cache) literature [?,?].
